System Calls

Kartik Gopalan
System Calls

- Modern CPUs support at least two levels of privileges:
  - User mode - application execute at this level
  - Supervisor mode - OS (kernel) code executes at this level

- **System calls**
  - Interface to allow User-level processes to safely invoke OS routines for privileged operations.
  - Safely transfer control from lower privilege level (user mode) to higher privilege level (supervisor mode), and back.
System Call table

• Protected entry points into the kernel for each system call
  ○ We don’t want application to randomly jump into any part of the OS code.

• Syscall table is usually implemented as an array of function pointers, where each function implements one system call

• Syscall table is indexed via system call number
System call invocation

1. System call is invoked via a special CPU instruction
   - Such as SYSENTER/int 0x80/lcall7/lcall27 etc.
   - The system call number and arguments passed via CPU registers and optionally stack.
2. CPU saves process execution state
3. CPU switches to higher privilege level
   - Jumps to an entry point in OS code.
4. OS indexes the system call table using the system call number
5. OS invokes the system call via a function pointer in the system call table.
   - For performance reasons, the system call usually executes in the execution context of
     the calling process, but in privileged mode.
   - Some operating systems may execute the system call in a separate execution context for
     better security.
6. If the syscall involves blocking I/O, the calling process may block while the I/O completes.
7. When syscall completes, the calling process is moved to ready state.
8. The saved process state is restored
9. Processor switches back to lower (user) privilege level using SYSEXIT/iret instructions
10. Process returns from the system call and continues.
Syscall Usage

- To make it easier to invoke system calls, OS writers normally provide a library that sits between programs and system call interface.
  - Libc, glibc, etc.

- This library provides wrapper routines

- Wrappers hide the low-level details of
  - Preparing arguments
  - Passing arguments to kernel
  - Switching to supervisor mode
  - Fetching and returning results to application.

- Helps to reduce OS dependency and increase portability of programs.
Implementing System Calls
Steps in writing a system call

- Create an entry for the system call in the kernel’s **syscall_table**
  - User processes trapping to the kernel (through SYS_ENTER or int 0x80) find the syscall function by indexing into this table.

- Write the system call code as a kernel function
  - Be careful when reading/writing to user-space
  - Use `copy_to_user()` or `copy_from_user()` routines.
    - These perform sanity checks.

- Generate/Use a user-level system call stub
  - Hides the complexity of making a system call from user applications.
  - See `man syscall`
Step 1: Create a sys_call_table entry (for 64-bit x86 machines)

- arch/x86/syscalls/syscall_64.tbl
  
  The format is:
  
  `<number> <abi> <name> <entry point>`

  The abi is "common", "64" or "x32" for this file.

  ... 309 common getcpu sys_getcpu
  310 64 process_vm_readv sys_process_vm_readv
  311 64 process_vm_writev sys_process_vm_writev
  312 common kcmp sys_kcmp
  313 common foo sys_foo
Step 2: Write the system call handler

- System call with no arguments and integer return value

  ```c
  asmlinkage int sys_foo(void) {
    printk(KERN_ALERT "I am foo. UID is %d\n", current->uid);
    return current->uid;
  }
  ```

- Syscall with one primitive argument

  ```c
  asmlinkage int sys_foo(int arg) {
    printk(KERN_ALERT "This is foo. Argument is %d\n", arg);
    return arg;
  }
  ```

- To see log: dmesg, /var/log/kern.log
Step 2: Write the system call handler (cont...)

- Verifying argument passed by user space

```c
asmlinkage long sys_close(unsigned int fd) {
    struct file * filp;
    struct files_struct *files = current->files;
    struct fdtable *fdt;
    spin_lock(&files->file_lock);
    fdt = files_fdtable(files);
    if (fd >= fdt->max_fds)
        goto out_unlock;
    filp = fdt->fd[fd];
    if (!filp)
        goto out_unlock;
    ...
    out_unlock:
    spin_unlock(&files->file_lock);
    return -EBADF;
}
```

- Call-by-reference argument
  - User-space pointer sent as argument.
  - Data to be copied back using the pointer.

```c
asmlinkage ssize_t sys_read (unsigned int fd, char __user * buf, size_t count) {
    ...
    if( !access_ok( VERIFY_WRITE, buf, count))
        return -EFAULT;
    ...
    return -EFAULT;
}
```
Example syscall implementation

```c
asmlinkage int sys_foo(void) {
    static int count = 0;
    printk(KERN_ALERT "Hello World! %d\n", count ++);
    return -EFAULT; // what happens to this return value?
}

EXPORT_SYMBOL(sys_foo);
```
Step 3: Invoke your new handler with syscall

- Use the **syscall(...) library function**.
  - Do a "man syscall" for details.

- For instance, for a no-argument system call named foo(), you'll call
  - `ret = syscall(__NR_sys_foo);`
  - *Assuming you've defined __NR_sys_foo earlier*

- For a 1 argument system call named foo(arg), you call
  - `ret = syscall(__NR_sys_foo, arg);`

- and so on for 2, 3, 4 arguments etc.

- For this method, check
Step 3: Invoke your new handler with syscall (cont...)

```c
#include <stdio.h>
#include <errno.h>
#include <unistd.h>
#include <linux/unistd.h>
#include <linux/unistd.h>

// define the new syscall number. Standard syscalls are defined in linux/unistd.h
#define __NR_sys_foo 333

int main(void)
{
    int ret;
    while(1) {
        // making the system call
        ret = syscall(__NR_sys_foo);
        printf("ret = %d errno = %d\n", ret, errno);
        sleep(1);
    }
    return 0;
}
```
